## ABSTRACT

The electronic structure and properties of $\mathrm{Cp}_{2} \mathrm{Ti}\left(\mathrm{C}_{6} \mathrm{H}_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)$ $\left(\mathrm{C}_{6} \mathrm{H}_{4}=\right.$ benzyne, $\left.\mathrm{n}=1-4\right)$ complexes have been explored using hybrid density functional B3LYP theory. Both aromatic natures and nucleus independent chemical shift (NICS) of the benzyne rings have been investigated. Among mono-, di-, and tri-fluorinated complexes, $o-\mathrm{F}, \mathrm{F} 14$, and $m$ H are the most stable isomers, respectively. NICS values calculated at the several points above the ring centers are consistent with those based on the relative energies of the complexes. The atoms in molecules (AIM) analysis indicates that $\Sigma \mathrm{Ti}-\mathrm{C}$ bond distance is well correlated with the electron density of a ring critical point ( $\Sigma \rho_{\text {rep }}$ ) in all species.

## INTRODUCTION

Benzyne has been the subject of many theoretical and experimental investigations ${ }^{[1-6]}$ because it is found as an intermediate of many important organic or biochemical reactions ${ }^{[3,7,8]}$. Since the first attempt for making metal complexes using benzyne by Wittig and Bickelhaupt in $1958{ }^{[9]}$, many benzyne complexes have been successfully prepared ${ }^{[10-13]}$. Benzyne complexes are strongly implicated as reactive intermediates in the thermal decomposition of perphenyl derivatives of the early transition elements, and of uranium and thorium; they can sometimes be isolated from such reactions. For example, $\mathrm{Cp}_{2} \mathrm{Ti}\left(\mathrm{C}_{6} \mathrm{H}_{4}\right)_{2}$ has been formed when $\mathrm{TiCl}_{2} \mathrm{Cp}_{2}$ is treated with o-bromofluorobenzene and magnesium ${ }^{[14]}$.

The structure and bonding of $\mathrm{Ni}\left(\mathrm{C}_{6} \mathrm{H}_{4 \mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)(\mathrm{CO})_{2}$ $\mathrm{C}_{6} \mathrm{H}_{4}=$ benzyne, $n=1-4$ ) complexes have been studied theoretically ${ }^{[15]}$. In the present study, the quantum chemical methods were used in order to increase a deeper insight into the structure and bonding of Ti $\left(\mathrm{C}_{6} \mathrm{H}_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)(\mathrm{CO})_{2}\left(\mathrm{C}_{6} \mathrm{H}_{4}=\right.$ benzyne, $\left.\mathrm{n}=1-4\right)$ complexes and phenomena of the substituent effect in a benzyne ring.

## Computational methods

All calculations were carried out with the Gaussian 03 suite of program ${ }^{[16]}$. Light atoms (C, H, O and F) were described by the standard 6-31G (d,p) basis set ${ }^{[17-}$ ${ }^{21]}$. Ti was described by the effective core potential (ECP) of Wadt and Hay pseudo-potential ${ }^{[22]}$ with a double- $\xi$ valance using the LANL2DZ basis set ${ }^{[23,24,25]}$.

## Full Paper

Geometry optimization was performed using Becke's hybrid three-parameter exchange functional and the nonlocal correlation functional of Lee, Yang, and Parr (B3LYP) ${ }^{[26]}$. A vibrational analysis was performed at each stationary point which corresponds to an energy minimum.

The nucleus-independent chemical shift (NICS) ${ }^{[27,28]}$ has been defined as the absolute magnetic shielding computed at the center of a ring in a molecule. NICS (0.0), NICS (0.5), NICS (1.0), NICS (1.5) and NICS (2.0) were calculated at 0 (center), $0.5,1.0,1.5$, and $2.0 \AA$ above the ring, respectively.

The AIM2000 program ${ }^{[29]}$ was used for the topological analysis of electron density, and the characteristics of ring critical points (RCPs) were taken into account: density at $R C P\left(\rho\left(r_{c}\right)\right)$, and its Laplacian $\left(\nabla^{2} \rho\left(\mathrm{r}_{\mathrm{c}}\right)\right)$.

## RESULT AND DISCUSSION

## Energetic aspect

Figure 1 shows the optimized geometries the all molecule. The calculated energy values of the compounds in this work are listed along with the energy ( E ), relative energy ( $\Delta \mathrm{E}$ ), and HOMO-LUMO gaps in TABLE 1. When the compounds are classified with geometric isomers, $o$-F, F14, and $m$-H are the most stable isomer in each group, and harder than the other isomers. As expected from the principles of minimum energy, and maximum HOMO-LUMO gaps (TABLE 3), that is, when an isomer changes from the most stable to other less stable species in most cases, the energy increases,

the HOMO-LUMO gaps decreases.

## Geometry

The structures of the $\mathrm{Cp}_{2} \mathrm{Ti}\left(\mathrm{C}_{6} \mathrm{H}_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)$ $\left(\mathrm{C}_{6} \mathrm{H}_{4}=\right.$ benzyne, $\left.\mathrm{n}=1-4\right)$ complexes were optimized by DFT calculations (Figure 1, TABLE 2). The C-C bond lengths in the benyne-Ti complexes seem to be related with the changes in aromaticity. The C1-C6 bond distance of benzyne ( $1.384 \AA$ ) becomes elongated to 1.394 $\AA \AA$ when benzyne forms a complex with $\mathrm{TiCp}_{2}$ in $\mathrm{H}_{4}$. In contrast, this bond tends to decrease as the number of F atoms increase in the complex if the most stable isomers of the fluorinated complexes are considered: 1.379 $\AA(\mathrm{o}-\mathrm{F}), 1.380 \AA(\mathrm{~F} 14), 1.381 \AA(\mathrm{~m}-\mathrm{H})$, and $1.376 \AA$ ( $\mathrm{F}_{4}$ ).
TABLE 2: The selected bond lengths $(\AA)$ for $\mathbf{C p}_{2} \mathbf{T i}\left(\mathbf{C}_{6} \mathbf{H}_{4 \mathrm{n}} \mathbf{F}_{\mathrm{n}}\right)$ ( $\mathrm{n}=1-4$ ) complexes.

The bond angles around Ti atom also show a systematic trend that the $\mathrm{C} 1-\mathrm{Ni}-\mathrm{C} 2$ bond angles increase decrease in the fluorinated complexes (except in $m$-F).

## Frontier orbitals

The HOMO and LUMO energies of the compounds in TABLE 3 show that all the Ti-complexes have lower HOMO-LUMO gap energies than those of $\mathrm{C}_{6} \mathrm{H}_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}(\mathrm{n}=0-4)$. On the other hand, these values to decrease as the number of F atoms increases.

## Nucleus-independent chemical shift (NICS)

As an effort to discuss the use of NICS as a measure of aromaticity, we have calculated NICS values from the center of the ring to $2.0 \AA$ above the plane along the $z$-axis of the benzyne ring. The shape of NICS

profile with respect to the distance from the ring center falls into two categories. In addition, for all species, we have localized both the NICS maxima and minima, and determined the distances to the center of the ring at which they occur (TABLE 4). For each benzyne, di-, tri-, and tetra-fluorinated species, the highest absolute value of NICS closes to the center of the ring. Both non- and mono-fluorinated species have a maximum about $0.5 \AA$ to the ring center. It is possible that induced magnetic fields generated by the $\sigma$-aromaticity are particularly large in the center of the ring. However, the molecular systems having $\pi$-aromaticity have a minimum NICS at the certain distances from the center of the ring. There is a linear correlation between NICS (0.0) and NICS (0.5) values in all complexes: $\mathrm{R}^{2}=$ 0.992 (Figure 2).

Figure 2 : Variations of NICS (0.0) andNICS (0.5) for $\mathrm{Cp}_{2} \mathbf{T i}$ $\left(\mathrm{C}_{6} \mathrm{H}_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)(\mathrm{n}=1-4)$ complexes.

intermolecular orbital interaction in the complex, particularly charge transfer. This is carried out by considering all possible interactions between filled donor and empty acceptor NBOs and estimating their energetic importance by second-order perturbation theory. For each donor NBO (i) and acceptor NBO (j), the stabilization energy $\mathrm{E}^{2}$ associated with electron delocalization between donor and acceptor is estimated as:
$E^{(2)}=-q_{i} \frac{\left(F_{i, j}\right)^{2}}{\varepsilon_{j}-\varepsilon_{i}}$
Where $q_{i}$ is the orbital occupancy, $\varepsilon_{\mathrm{i}}$, $\varepsilon_{\mathrm{j}}$ are diagonal elements and $\mathrm{F}_{\mathrm{ij}}$ is the off-diagonal NBO Fock matrix element.

As illustrated in the NBO analysis, the Ti- $\mathrm{C}_{\text {benynne }}$ bonds of the complexes show the $\sigma$ bonds of $\mathrm{Ni}-\mathrm{C}_{\text {benzyne }}$ bonds of the complexes are composed of $\mathrm{sp}^{m} \mathrm{~d}^{\mathrm{n}}$ hybrid orbital of nickel and $\mathrm{sp}^{\mathrm{n}}$ hybrid orbital of the carbine carbon (TABLE 5). The occupation numbers of $\sigma$ (Ti-
$\mathrm{C}_{\text {benzyne }}$ ) are given in TABLE 5. This values decrease in fluorinated complexes. There is a good relationship between <occupancy> and <r(Ti-C bennyne ) > (Figure3).

Figure 3 : Variations of <occupancy> of $\mathrm{TiC}_{\text {benyne }}$ and $<\mathbf{r}$ $\mathrm{TiC}_{\text {benyme }}>$ for $\mathrm{Cp}_{2} \mathbf{T i}\left(\mathrm{C}_{6} \mathbf{H}_{4 \cdot \mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)(\mathbf{n}=1-4)$ complexes.

TABLE 6 gathers the most strongest donor-acceptor interaction energy ( $\mathrm{E}^{2}$ ) for $\sigma_{\mathrm{n}}(\mathrm{C} 3) \rightarrow \pi^{*}(\mathrm{Ti})$ (in non-fluorinated complexes) and $\pi^{*}\left(\mathrm{C}^{\prime}-\mathrm{C} 4{ }^{\prime}\right) \rightarrow$ $\pi^{*}\left(\mathrm{C} 1^{\prime}-\mathrm{C} 5^{\prime}\right)$ (in fluorinated complexes). The minimum correspond to tetra-fluorinated complex.

## QTAIM analysis

As it is difficult to separate the $\sigma$ and $\pi$ contributions to the electron density at the bond critical point, the $\rho(\mathrm{r})$ values can be used to evaluate bond strength for different types of bonds. The different values of $\rho(\mathrm{r})$ and $\nabla^{2} \rho(\mathrm{r})$ for the Ti-C $\mathrm{C}_{\text {benyne }}$ bonds evidently indicate the relative Ti-C $\mathrm{C}_{\text {benzyne }}$ bond strengths (TABLE 7). On the other hand, the Ti- $\mathrm{C}_{\text {benzyne }}$ bonds in all structures have positive values of $\nabla^{2} \rho(\mathrm{r})$ which is indicative of the close shell interaction. The value of electron density and its Laplacian estimated at bond critical point of Ti- $\mathrm{C}_{\text {benzne }}$ correlate very well with the strength of the bond, as well as with its length, since, as it is well known, both the strength and length of a bond are mutually dependent. A good relationship is present between the average electron density of Ti- $\mathrm{C}_{\text {benzyne }}$ values and average bond distance of Ti- $\mathrm{C}_{\text {benyne }}$ ( $\mathrm{R}^{2}=0.976$, Figure 4). Similarity, $\Sigma \nabla^{2} \rho\left(\right.$ Ti- $\left.\mathrm{C}_{\text {benzyne }}\right)$ values obeys a linear relationship ( $\mathrm{R}^{2}=0.851$, Figure 5), too.

The bond ellipticity is defined as $\varepsilon=\left(\lambda_{1} / \lambda_{2}\right)-1$, where $\left|\lambda_{1}\right| \geq\left|\lambda_{2}\right|$. It provides a quantitative measurement of the $\pi$ character of the bond. The plane of the $\pi$ distribution is uniquely specifies by the direction of the axis associated with the curvature of smallest magnitude, $\lambda_{2}$. The $\varepsilon\left(\mathrm{Ti}^{\left.-\mathrm{C}_{\text {benzyne }}\right)}\right.$ values show that the $\mathrm{Ni}-\mathrm{C}$

TABLE 5: Occupancy of natural orbitals (NBOs) and hybrids of Ti- $\mathrm{C}_{\text {benzne }}$ bonds of $\mathrm{C}_{6} \mathrm{H}_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}$ and $\mathrm{Cp}_{2} \mathrm{Ti}^{\left(\mathrm{C}_{6} H_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)\left(\mathrm{C}_{6} \mathrm{H}_{4}=\right.}$ benzyne, $n=1$-4) complexes.

bond in fluorinated rings has a smaller $\pi$-character in comparison with H 4 (TABLE 7).

Further useful information on the chemical bond properties is obtainable from the total electron energy density $(H(\rho))$ and its components, a kinetic electron energy density ( $G(\rho)$, positive by definition) and a po-

Figure 4 : Variations of $<\rho>$ of TiC $_{\text {benynne }}$ and $<\mathrm{r} \mathrm{TiC}_{\text {benzyne }}>$ for $\mathrm{Cp}_{2} \mathbf{T i}\left(\mathrm{C}_{6} \mathrm{H}_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)(\mathrm{n}=1-4)$ complexes.
tential electron energy density $(\mathrm{V}(\rho)$, negative by definition). The following relation is known for $\mathrm{H}(\rho)$ and its components:
$H(\rho)=G(\rho)+V(\rho)$
For the strong covalent interactions (Ti- $\mathrm{C}_{\text {benzyne }}$ ), V ( $\rho$ ) dominates over the kinetic energy density $(\mathrm{G}(\rho))$ and $H(\rho)<0$. This usually accompany with $\nabla^{2} \rho>0$ for $H$ ( $\rho)>0$.

At the ring critical point of benzyne, both the electron density $\rho(3,+1)$ and Laplacian of electron density

## CONCLUSION

We investigated the structure, properties and bonding of the $\mathrm{Cp}_{2} \mathrm{Ti}\left(\mathrm{C}_{6} \mathrm{H}_{4-\mathrm{n}} \mathrm{F}_{\mathrm{n}}\right)\left(\mathrm{C}_{6} \mathrm{H}_{4}=\right.$ benzyne, $\left.\mathrm{n}=1-4\right)$ complexes. The results suggest that o-F,F14, m-H isomers are most stable among the mono-, di-, tri-fluorinated complexes, respectively. The NICS calculations confirmed the aromaticity in the benzyne rings of the compounds. Using the analyses of both electron densities and energy densities, we could explain the characters of the $\mathrm{Ti}-\mathrm{C}$ bonds in complexes.
